C Programming Basic – week 13

Topics of this week

- String pattern matching algorithms
 - Naive algorithm
 - Knuth-Morris-Pratt algorithm
 - Boyer-Moore algorithm
- Exercises

String matching problem

- Let P be a string of size m
 - A substring P[i .. j] of P is the subsequence of P consisting of the characters with ranks between i and j
 - A prefix of P is a substring of the type P[0 .. i]
 - A suffix of P is a substring of the type P[i ..m 1]
- Given strings T (text) and P (pattern), the pattern matching problem consists of finding a substring of T equal to P
- Applications:
 - Text editors, Search engines, Biological research

Brute Force Matching

- The brute-force pattern matching algorithm compares the pattern P with the text T for each possible shift of P relative to T, until either
 - a match is found, or
 - all placements of the pattern have been tried
- Brute-force pattern matching runs in time O(nm)
- Example of worst case:
 - T = aaa ... ah
 - -P = aaah
 - may occur in images and DNA sequences
 - unlikely in English text

Algorithm

Algorithm BruteForceMatch(T, P)

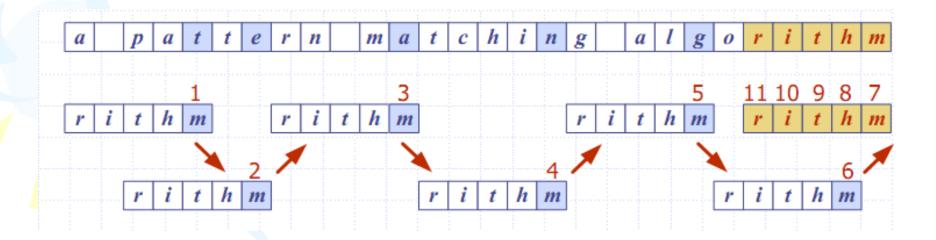

```
// Input text T of size n and pattern P of size m
// Output starting index of a substring of T equal to P or
if no such substring exists
  for i \leftarrow 0 to n - m {
     test shift i of the pattern
  j ← 0
  while j < m \land T[i + j] = P[j]
  j ← j + 1
  if j = m
     return i {match at i}
  else
  break while loop {mismatch}
return -1 {no match anywhere}
```

Exercise 13.1

- Make a random string that has about 2000 characters consisting of a set of characters..
- For example:
 - set of characters: abcdef
 - string: abcadacaeeeffaadbfacddedcedfbeccae...
- Write the program that searches the pattern, for example "aadbf", from the string.
- Note: use Simple searching string Algorithm

Boyer-Moore Heuristics

- The Boyer-Moore's pattern matching algorithm is based on two heuristics
- Looking-glass heuristic: Compare P with a subsequence of T
- moving backwards
- Character-jump heuristic: When a mismatch occurs at T[i] = c
 - If P contains c, shift P to align the last occurrence of c in P with T[i]
 - Else, shift P to align P[0] with T[i + 1]

Last-Occurrence Function

- Boyer-Moore's algorithm preprocesses the pattern P and the alphabet Σ to build the last-occurrence function L mapping Σ to integers, where L(c) is defined as
 - the largest index i such that P[i] = c or
 - 1 if no such index exists
- Example:

$$-\Sigma = \{a, b, c, d\}$$

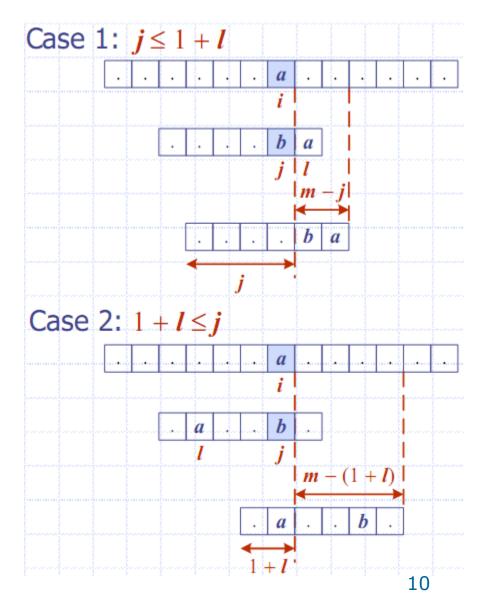

- P = abacab

С	a	b	С	d
L(C)	4	5	3	-1

- The last-occurrence function can be represented by an array indexed by the numeric codes of the characters
- The last-occurrence function can be computed in time O(m + s), where m is the size of P and s is the size of Σ

Algorithm Boyer Moore

```
Algorithm BoyerMooreMatch(T, P, \Sigma)
   L \leftarrow lastOccurenceFunction(P, \Sigma)
    i \leftarrow m-1
   j \leftarrow m - 1
   repeat
    if T[i] = P[j]
         if j = 0
         return i { match at i }
         else
         i \leftarrow i - 1
        j \leftarrow j - 1
    else
    { character-jump }
         l \leftarrow L/T/i
         i \leftarrow i + m - min(j, 1 + l)
         j \leftarrow m-1
    until i > n - 1
    return -1 \{ no match \}
```

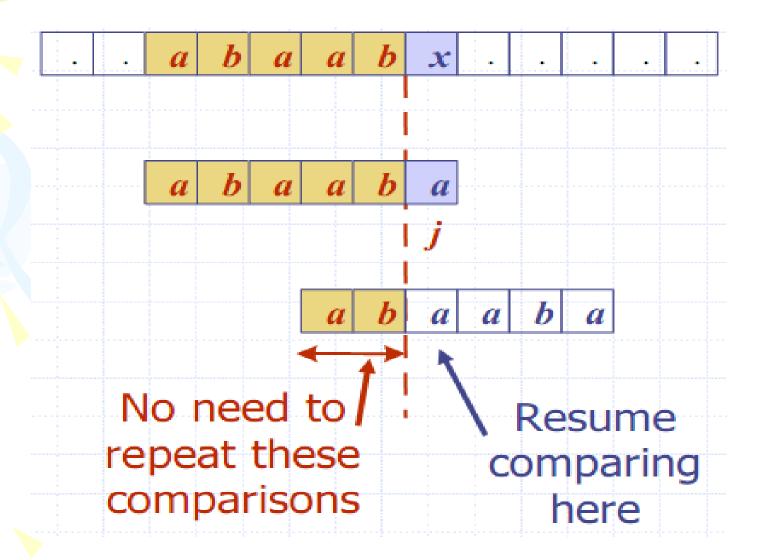

Exercise 13.2

- Make a random string that has about 2000 characters consisting of a set of characters.
- set of characters: abcdef
- string:
 abcadacaeeeffaadbfacddedcedfbeccae...
- Write the program that search the pattern, for example "aadbf", from the string.
- Note: use Boyer-Moore Algorithm

KMP string matching

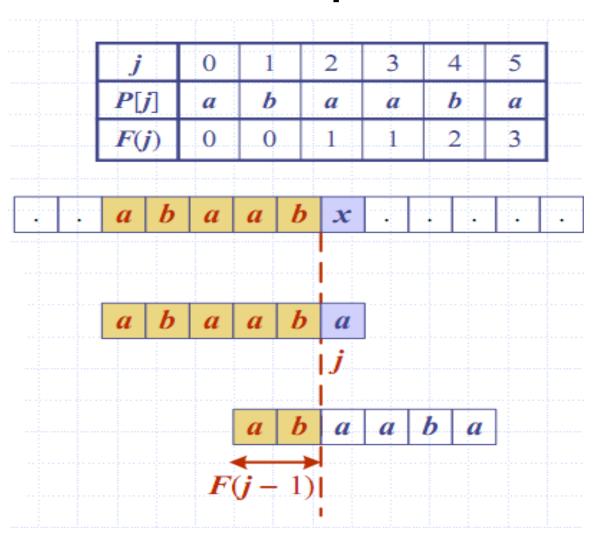

- Knuth-Morris-Pratt's algorithm compares the pattern to the text in left-to-right, but shifts the pattern more intelligently than the bruteforce algorithm.
- When a mismatch occurs, what is the most we can shift the pattern so as to avoid redundant comparisons?
- Answer: the largest prefix of P[0..j] that is a suffix of P[1..j]

KMP Failure Function

- Knuth-Morris-Pratt's algorithm preprocesses the pattern to find matches of prefixes of the pattern with the pattern itself
- The failure function F(j) is defined as the size of the largest prefix of P[0..j] that is also a suffix of P[1..j]
- Knuth-Morris-Pratt's algorithm modifies the brute-force algorithm so that if a mismatch occurs at P[j] ≠ T[i] we set

$$j \leftarrow F(j-1)$$

```
Algorithm failureFunction(P)
   F[0] ← 0
   i \leftarrow 1
  i ← 0
   while i < m
      if P[i] = P[i]
       {we have matched j + 1 chars}
          F[i] \leftarrow i + 1
          i \leftarrow i + 1
          j \leftarrow j + 1
       else if j > 0 then
       {use failure function to shift P}
          j \leftarrow F[j-1]
       else
          F[i] \leftarrow 0 \{ no match \}
          i \leftarrow i + 1
```

Exercise 13.3

- Repeat the exercise 13.2 using the KMP algorithm.
- Calculate the number of comparisons.

The KMP algorithm

- The failure function can be represented by an array and can be computed in O(m) time
- At each iteration of the while-loop, either
 - i increases by one, or
 - the shift amount i j increases by at least one (observe that F(j 1) < j)
- Hence, there are no more than 2n iterations of the while-loop
- Thus, KMP's algorithm runs in optimal time
 O(m + n)

```
Algorithm KMPMatch(T, P)
   F \leftarrow failureFunction(P)
   i \leftarrow 0
   j \leftarrow 0
   while i < n
         if T[i] = P[j]
              if j = m - 1
                   return i - j \{ match \}
              else
                   i \leftarrow i + 1
                   j \leftarrow j + 1
         else
              if j > 0
                  j \leftarrow F[j-1]
              else
                   i \leftarrow i + 1
   return -1 { no match }
```
